ABSTRACT

The increasing severity of environmental challenges highlights the need for a transformative approach to environmental education. Conventional approaches often emphasise environmental knowledge, with limited attention to ecological values, concern and responsibility. This conceptual paper explores the integration of ecocentrism and experiential learning as complementary foundations for transforming environmental education. Ecocentrism emphasises the intrinsic value of nature, ecological interconnectedness and respect for biodiversity, while experiential learning promotes learning through experience, reflection, conceptual understanding and action. The paper proposes an Integrated Ecocentric Experiential Learning Framework comprising five interconnected processes: direct experience with nature, ecological reflection, ecocentric conceptual understanding, ecological engagement and responsible action, and evaluation and reflective transformation. The framework aims to promote ecological understanding, environmental concern, respect for all forms of life and pro-environmental attitudes among school students. It also highlights implications for school science education, curriculum development and teacher preparation. The paper argues that integrating ecocentric philosophy with experiential pedagogy can transform environmental education from knowledge transmission into a value-oriented and action-based process that nurtures ecologically

responsible individuals.

Environmental degradation has emerged as a major challenge confronting contemporary society. Climate change, biodiversity loss, deforestation, pollution, habitat destruction, and unsustainable resource exploitation threaten ecological stability and the well-being of living organisms. Addressing these challenges requires not only scientific knowledge and technological interventions but also changes in human values, attitudes, and behaviours towards nature. Education plays a significant role in developing environmental awareness, ecological understanding, and responsibility. The Tbilisi Declaration (UNESCO-UNEP, 1978) identified awareness, knowledge, attitudes, skills, and participation as essential objectives of environmental education. Similarly, Sustainable Development Goal 4, particularly Target 4.7, and UNESCO (2017) emphasise developing the knowledge, values, and competencies necessary for sustainable development. These perspectives highlight the need to move beyond information transmission towards meaningful engagement with the natural environment.

Although environmental knowledge is essential, knowledge acquisition alone does not necessarily lead to environmental concern or responsible behaviour. Conventional environmental education often emphasises textbook-based explanations and theoretical understanding, providing limited opportunities for direct interaction with nature, reflection on ecological relationships, and practical environmental engagement. Moreover, nature is frequently presented from a human-centred perspective, emphasising its usefulness to human beings rather than its intrinsic value. Such an approach may inadequately develop appreciation for non-human life and ecological interconnectedness. Therefore, environmental education requires a broader philosophical and pedagogical orientation that integrates knowledge with ecological values, concern, and responsibility.

Ecocentrism offers an important philosophical foundation for this transformation. It recognises the intrinsic value of nature, respects biodiversity, emphasises ecological interconnectedness, and considers human beings as integral members of the wider ecological community. Molina-Motos (2019) highlights the significance of ecophilosophical principles in developing environmental education grounded in respect for the natural world. Developing ecological values and pro-environmental attitudes also requires meaningful experiences that engage learners cognitively, emotionally, and practically. Direct interaction with natural environments can help students appreciate biodiversity, understand ecological relationships, and develop connections with nature. Rosa and Collado (2019) highlight the relationship between experiences in nature and environmental attitudes and behaviours. Thus, environmental education should encourage learners not

merely to understand environmental problems but also to value nature and develop a willingness to protect it.

In this context, integrating ecocentrism and experiential learning offers a meaningful direction for transforming environmental education. Ecocentrism provides the philosophical foundation by emphasising the intrinsic value of nature and ecological responsibility, while experiential learning provides the pedagogical process through which these values can be explored and developed. According to Kolb (1984), experiential learning involves four interconnected stages: Concrete Experience, Reflective Observation, Abstract Conceptualisation, and Active Experimentation. Through this cycle, learners engage in experiences, reflect on their observations, develop conceptual understanding, and apply their learning in new situations. Nature walks, biodiversity observations, ecological investigations, and environmental projects can provide authentic contexts for this process. For example, observing a local pond enables students to explore organism diversity and ecological relationships, while reflection and conservation activities can strengthen their understanding and sense of responsibility. However, experiences need to be supported by reflection, conceptual learning, and meaningful action to contribute to deeper ecological understanding.

In view of these considerations, this conceptual paper explores the integration of ecocentrism and experiential learning as a transformative approach to environmental education, particularly in school contexts. It examines their philosophical and pedagogical foundations and proposes an Integrated Ecocentric Experiential Learning Framework (IEELF) comprising five interconnected dimensions: Direct Experience with Nature, Ecological Reflection, Ecocentric Conceptual Understanding, Ecological Engagement and Responsible Action, and Evaluation and Reflective Transformation. The paper argues that this integration offers a conceptual foundation for moving environmental education beyond knowledge-centred instruction towards an experiential, value-oriented, and action-based approach that nurtures ecological values and pro-environmental attitudes among school students.

Understanding Ecocentrism in Environmental Education

Ecocentrism is an environmental philosophy that recognises the intrinsic value of nature and considers human beings as integral members of the ecological community. Unlike anthropocentrism, which views nature primarily in terms of its usefulness to humans, ecocentrism emphasises the importance of all living organisms, ecosystems, and natural processes (Naess, 1973; Leopold, 1949). It promotes an ethical relationship with nature based on interconnectedness, coexistence, and respect for all forms of life.A central principle of ecocentrism is the **intrinsic value of nature**, which recognises that plants, animals, and

ecosystems possess worth beyond their usefulness to humans. It also emphasises **ecological interconnectedness,** highlighting the relationships among living organisms and their physical environments. Changes in one component of an ecosystem can influence the entire ecological system. Therefore, recognising these relationships is essential for developing a holistic understanding of nature (Leopold, 1949; Molina-Motos, 2019).

Ecocentrism further promotes **respect for biodiversity and all forms of life**, recognising the ecological significance of different organisms and habitats. The principle of **human–nature interdependence** highlights that human well-being is closely connected with the health of natural systems. It also emphasises **ecological responsibility**, encouraging individuals to minimise environmental harm and participate in conservation and sustainable practices (Naess, 1973; Molina-Motos, 2019). These principles provide an important philosophical foundation for transformative environmental education. Integrating ecocentrism into education can encourage learners to move beyond human-centred perspectives and develop ecological awareness, respect for nature, environmental concern, and pro-environmental attitudes. When combined with experiential learning, these values can be developed through direct interaction with nature, reflection, and responsible environmental action (Molina-Motos, 2019).

Experiential Learning: A Pedagogical Perspective

Experiential learning is an educational approach that emphasises learning through direct experience, active participation, reflection, and the practical application of knowledge. It positions learners at the centre of the learning process, encouraging them to explore situations, reflect on experiences, construct understanding, and apply knowledge in real-life contexts. Unlike approaches that primarily focus on information transmission, experiential learning promotes meaningful engagement with the surrounding environment. This makes it particularly relevant to environmental education, where ecological knowledge and values can be developed through direct interaction with nature.

A significant theoretical contribution to experiential learning was made by Kolb (1984) through his Experiential Learning Theory (ELT), which conceptualises learning as a process of creating knowledge through the transformation of experience. The theory comprises four interconnected stages: Concrete Experience, Reflective Observation, Abstract Conceptualisation, and Active Experimentation. These stages form a continuous cycle through which learners experience situations, reflect on them, develop conceptual understanding, and apply their learning in new contexts.

Concrete Experience involves direct participation in an activity or situation. In environmental education, students may explore school gardens, observe plants and animals, visit ponds, undertake nature walks, or investigate local environmental issues. Such experiences provide opportunities to encounter ecological processes and develop meaningful connections with nature.

Reflective Observation involves examining and interpreting experiences through observation, questioning, discussion, and reflection. Students may reflect on the relationships among organisms, the effects of pollution, biodiversity loss, and the consequences of human activities on ecosystems. Reflective journals and group discussions can help learners develop deeper insights from their experiences.

Abstract Conceptualisation enables learners to develop concepts and explanations based on their reflections. For example, observations of organisms in a pond may lead to an understanding of food chains, food webs, biodiversity, ecological balance, and interdependence. This stage connects personal experiences with scientific and ecological knowledge.

Active Experimentation involves applying acquired knowledge to practical situations. Students may develop biodiversity gardens, prepare waste-management plans, undertake water-conservation activities, or participate in habitat-protection projects. Such activities provide opportunities to translate ecological understanding into responsible environmental practices.

The four stages are interconnected and cyclical, as each new action generates further experiences for learning. In environmental education, this process enables students to connect observation, reflection, scientific understanding, and practical engagement. Nature-based activities such as biodiversity surveys, school gardening, ecological investigations, and community projects provide authentic learning contexts in which abstract environmental concepts can be related to familiar situations.

However, direct experiences alone may not ensure meaningful learning. They need to be supported by structured reflection, conceptual understanding, and opportunities for responsible action. When experiential learning is integrated with ecocentric principles, it can encourage learners to recognise the intrinsic value of nature, understand ecological interconnectedness, respect biodiversity, and develop ecological responsibility. Thus, experiential learning provides a pedagogical foundation for transforming environmental education into an active, reflective, and value-oriented process that connects environmental knowledge with meaningful experiences and responsible action.

The Convergence of Experiential Learning and Ecocentrism

The integration of experiential learning and ecocentrism offers a meaningful theoretical foundation for developing a transformative approach to environmental education. Although the two perspectives emerge from different theoretical traditions, they share a common emphasis on developing a meaningful relationship between human beings and the natural environment. Ecocentrism provides the philosophical foundation by recognising the intrinsic value of nature, ecological interconnectedness, respect for biodiversity, and human responsibility towards the environment. Experiential learning, on the other hand, provides a pedagogical process through which learners can understand and internalise these ecological principles through direct experiences, reflection, conceptual understanding, and practical engagement. Their convergence creates opportunities to move environmental education beyond the acquisition of factual knowledge towards the development of ecological values, awareness, concern, and responsible action.

Experience as a Pathway to Ecological Understanding

Direct experience provides an important starting point for developing ecological understanding. Through meaningful interaction with the natural environment, learners can observe living organisms, explore habitats, identify environmental changes, and recognise relationships among different components of ecosystems. Such experiences enable students to encounter nature as a living and interconnected system rather than as a collection of separate objects or resources. For example, observing a school garden, exploring a nearby pond, or participating in a biodiversity walk can help learners recognise the variety of life and the relationships that sustain ecological systems. When these experiences are guided by ecocentric principles, learners are encouraged to appreciate nature beyond its usefulness to human beings and recognise the intrinsic value of different forms of life.

Reflection as a Means of Developing Ecological Awareness and Concern

Experience alone may not automatically lead to ecological awareness or responsible attitudes. Reflection enables learners to examine their experiences, question existing assumptions, and develop a deeper understanding of environmental relationships and problems. By reflecting on observations of habitat destruction, pollution, declining biodiversity, or the careless use of natural resources, students can consider the consequences of human activities for other living organisms and ecosystems. Reflective discussions, group interactions, journals, and classroom presentations can help learners develop sensitivity towards environmental issues. From an ecocentric perspective, reflection also encourages students to reconsider human-centred attitudes and recognise their responsibilities as members of the ecological community. Thus, reflection connects personal experiences with environmental awareness and concern.

Conceptual Learning for Understanding Ecological Relationships

Conceptual learning enables students to organise their experiences and reflections into meaningful ecological knowledge. Through this process, learners develop an understanding of concepts such as biodiversity, food chains, food webs, ecological balance, interdependence, ecosystem functioning, and sustainability. These concepts help explain the relationships among organisms and between living and non-living components of the environment. For instance, after observing different organisms in a pond, students can explore how plants, insects, fish, microorganisms, water, and other elements contribute to the functioning of the ecosystem. An ecocentric orientation encourages learners to understand these relationships holistically and recognise that each component has significance within the larger ecological community. Consequently, conceptual learning becomes a means of developing an ecological worldview rather than merely memorising scientific information.

Practical Engagement for Developing Environmental Responsibility

Practical engagement provides opportunities for learners to apply their ecological understanding in real-life situations. Through environmental projects, conservation activities, waste-management programmes, school gardening, water-conservation initiatives, and biodiversity protection activities, students can translate their learning into responsible practices. Such activities encourage active participation in addressing environmental concerns and help learners recognise their capacity to contribute to ecological well-being. From an ecocentric perspective, these actions should not be motivated solely by human benefits but should also reflect respect for other forms of life and the integrity of ecological systems. Practical engagement therefore strengthens the connection between ecological knowledge, values, and responsible environmental behaviour.

Connecting Personal Experiences with Ecological Values

The convergence of experiential learning and ecocentrism also highlights the importance of connecting individual experiences with broader ecological values. Personal encounters with nature can become meaningful learning opportunities when learners are encouraged to recognise the intrinsic value of living organisms, appreciate biodiversity, understand ecological interconnectedness, and reflect on their relationship with the natural world. For example, caring for a plant, observing birds, exploring a local habitat, or participating in a conservation activity can help students develop appreciation and concern for nature. Through reflection and guided learning, these experiences can be connected with values such as respect for life, coexistence, sustainability, and ecological responsibility. In this way, ecological values are

not introduced merely as abstract principles but are developed through meaningful engagement with the environment.

The convergence of experiential learning and ecocentrism therefore establishes a complementary relationship between philosophical orientation and pedagogical practice. Ecocentrism provides the value framework that guides learners towards recognising the worth of nature and their interconnectedness with the ecological community. Experiential learning provides the systematic learning process through which these values can be explored, understood, reflected upon, and translated into action. Together, they offer a pathway for environmental education that integrates experience, reflection, ecological understanding, and responsible engagement. This integrated perspective can contribute to the development of learners who not only understand environmental issues but also demonstrate respect, concern, and responsibility towards the natural world.

Promoting Ecological Values and Pro-Environmental Attitudes

The development of ecological values and pro-environmental attitudes is a central goal of transformative environmental education. Beyond imparting scientific knowledge and environmental awareness, education should nurture appreciation, concern, and responsibility towards the natural world. The integration of ecocentrism and experiential learning provides opportunities to develop these qualities through direct interaction with nature, reflection, ecological understanding, and responsible action. The proposed Integrated Ecocentric Experiential Learning Framework (IEELF) seeks to encourage an ecologically sensitive worldview in which learners recognise their relationship with and responsibility towards the wider ecological community. Recognition of the intrinsic value of nature involves understanding that plants, animals, and ecosystems possess worth independent of their usefulness to human beings. An ecocentric perspective encourages learners to appreciate all forms of life as valuable members of the ecological community. Nature observation, habitat exploration, and biodiversity studies can help students develop appreciation for nature beyond its economic or utilitarian benefits. Such experiences, supported by reflection, can nurture respect and care for the natural environment.

Respect for biodiversity involves recognising the value of different living organisms and their contributions to ecological systems. Through nature walks, biodiversity surveys, field visits, and conservation activities, students can explore the diversity of life and understand the interdependence among organisms. These experiences can foster appreciation for different forms of life, including those often overlooked, and encourage a commitment to biodiversity conservation.

Implications for School Education

The integration of ecocentrism and experiential learning has significant implications for the teaching and learning of environmental education in schools. It provides an opportunity to move beyond textbook-centred instruction and develop learning experiences that connect scientific knowledge with ecological values, environmental concern, and responsible action. The proposed Integrated Ecocentric Experiential Learning Framework offers a pedagogical direction for transforming school environmental education into a more participatory, experience-based, and value-oriented process. Its implementation requires appropriate integration of ecocentric perspectives into school subjects, meaningful engagement with nature, project-based activities, teacher preparation, and curriculum and assessment practices.

Integrating Ecocentric Perspectives into School Science

School science provides considerable opportunities for introducing ecocentric perspectives through topics related to biodiversity, ecosystems, natural resources, food chains, environmental pollution, conservation, and sustainability. However, the teaching of these topics should extend beyond the explanation of scientific facts and the usefulness of nature to human beings. An ecocentric perspective encourages teachers to highlight the intrinsic value of living organisms, ecological interconnectedness, respect for biodiversity, and the interdependence of humans and other components of nature. For example, while teaching biodiversity, students can be encouraged to understand the ecological significance of different organisms rather than considering them only in terms of their benefits to humans. Such integration can promote a holistic understanding of ecological systems and develop respect for all forms of life.

Nature-Based and Field-Based Learning

Nature-based and field-based learning provide valuable opportunities for students to engage directly with their surroundings and understand ecological processes through observation and exploration. School gardens, nearby ponds, agricultural fields, wetlands, forests, and other local ecosystems can function as meaningful learning environments. Activities such as nature walks, biodiversity observation, habitat studies, and ecological investigations enable students to connect classroom concepts with real-world environmental situations. These experiences can help learners recognise ecological relationships, appreciate biodiversity, and develop emotional connections with nature. Teachers can use the immediate school and community environments as accessible learning resources, making environmental education locally relevant and meaningful. Such experiences should be accompanied by reflection and discussion to connect observations with broader ecological principles and values.

Project-Based Environmental Activities

Project-based environmental activities can support the practical application of ecological knowledge and values. Through collaborative projects, students can identify environmental concerns, investigate their causes, develop possible solutions, and participate in activities that contribute to environmental protection. Examples include school biodiversity gardens, waste audits, waste-reduction campaigns, water-conservation projects, composting initiatives, local habitat documentation, and plastic-free school programmes. These activities encourage problem-solving, collaboration, decision-making, and active participation. They also provide opportunities for learners to experience ecological responsibility through individual and collective action. From an ecocentric perspective, such projects should emphasise the protection of ecological communities and the value of different forms of life, rather than focusing exclusively on human convenience or resource efficiency.

Teacher Preparation and Pedagogical Competencies

The successful implementation of an ecocentric experiential approach depends significantly on teachers' knowledge, attitudes, and pedagogical competencies. Teachers need a sound understanding of ecocentric principles, ecological concepts, experiential learning processes, and environmental education objectives. They should be able to organise nature-based learning experiences, facilitate reflective discussions, guide ecological investigations, manage project-based activities, and connect students' experiences with scientific concepts and environmental values. Teacher education programmes and professional development initiatives should therefore provide opportunities for developing both conceptual understanding and practical competencies related to ecocentric and experiential pedagogy. Teachers should also be prepared to use local environmental resources, address diverse learner needs, ensure safety during field-based activities, and encourage inclusive participation. Their role extends beyond transmitting environmental information to facilitating meaningful interactions between learners and the natural world.

Curriculum and Assessment Implications

The integration of ecocentric and experiential perspectives also requires appropriate consideration in curriculum planning and assessment. Environmental concepts and values should be meaningfully integrated across relevant school subjects rather than treated as isolated textbook topics. Curricula can provide opportunities for interdisciplinary learning, local environmental investigations, field-based experiences, and sustained environmental projects. Adequate flexibility in instructional time and access to local learning resources would support the implementation of such activities.

Assessment practices should also extend beyond written examinations that primarily measure factual knowledge. A broader assessment approach can consider students' ecological understanding, appreciation of biodiversity, environmental concern, sense of responsibility, and participation in pro-environmental activities. Reflective journals, project reports, observation schedules, portfolios, presentations, self-assessment, and peer assessment can provide evidence of different dimensions of learning. Knowledge, attitudes, values, and behaviour should be assessed through appropriate and distinct indicators. In particular, participation in a single environmental activity should not automatically be interpreted as evidence of sustained pro-environmental behaviour. Assessment should therefore consider both immediate learning outcomes and opportunities for continued environmental engagement.

Overall, the integration of ecocentrism and experiential learning offers a valuable direction for strengthening environmental education in schools. It encourages the transformation of school science from a predominantly content-oriented subject into a learning experience that connects scientific understanding with ecological values and responsible practices. Through curriculum integration, nature-based experiences, project activities, competent teachers, and holistic assessment, schools can create meaningful opportunities for students to develop a respectful and responsible relationship with the natural environment. Such an approach can contribute to preparing environmentally conscious learners who recognise their place within the ecological community and are willing to participate in protecting its well-being.

Challenges and Considerations

Although integrating ecocentrism and experiential learning offers opportunities to transform environmental education, its implementation in schools may involve practical and pedagogical challenges. The proposed Integrated Ecocentric Experiential Learning Framework (IEELF) requires direct interaction with nature, reflection, conceptual understanding, and practical environmental engagement. However, school infrastructure, curriculum demands, resource availability, and teachers' preparedness may influence its implementation. Recognising these challenges is essential for ensuring the feasibility and sustainability of the framework.

Limited Opportunities for Outdoor Learning

Restricted outdoor spaces, urban surroundings, safety concerns, weather conditions, and institutional limitations may reduce opportunities for direct interaction with nature. Consequently, students may depend more on textbook descriptions than on authentic ecological experiences. However, nature-based learning does not necessarily require access to distant natural environments. School gardens, nearby ponds,

playgrounds, roadside vegetation, and local community spaces can serve as accessible learning environments. Photographs, specimens, nature journals, and locally available resources can also support learning when outdoor activities are not feasible.

Time and Curriculum Constraints

Prescribed curricular content, structured timetables, and examination-oriented practices may restrict opportunities for field investigations, reflective discussions, and environmental projects. These activities often require more time than conventional classroom instruction. Integrating ecological experiences into existing curriculum topics, adopting interdisciplinary approaches, and organising short nature-based investigations can help address these constraints. Such integration can make experiential learning a meaningful part of regular classroom instruction rather than an additional curricular burden.

Availability of Teaching-Learning Resources

Limited access to transportation, laboratory equipment, digital resources, and field-study facilities may affect the organisation of ecological investigations. Nevertheless, experiential environmental education need not depend on expensive resources. School surroundings, recycled materials, photographs, observation records, and community knowledge can provide meaningful learning opportunities. Collaboration with local environmental organisations and community members may further strengthen available resources.

Teachers' Understanding of Ecocentric Philosophy

Teachers' familiarity with ecocentric principles is essential for meaningful implementation. Conventional environmental education may emphasise the usefulness of natural resources and the effects of environmental degradation on human welfare. In contrast, ecocentrism requires an understanding of the intrinsic value of nature, ecological interconnectedness, respect for biodiversity, and responsibility towards all forms of life. Teacher education and professional development programmes should therefore strengthen both ecocentric understanding and the pedagogical competencies required to organise nature-based activities, facilitate reflection, and connect experiences with ecological concepts and values.

Assessing Values and Behavioural Outcomes

Assessing ecological values, environmental concern, and pro-environmental behaviour is challenging because these constructs cannot be adequately measured through written examinations alone. Students' expressed attitudes may not always correspond to their actual environmental practices. Therefore, assessment should incorporate multiple methods, including attitude scales, reflective journals, classroom

observations, project reports, interviews, and self-assessment. Repeated observations and follow-up assessments may also help distinguish temporary participation in environmental activities from sustained pro-environmental behaviour.

Addressing these challenges requires a flexible and context-sensitive approach supported by appropriate resources, curriculum opportunities, institutional support, and teacher preparation. The framework should be adapted to the geographical, social, cultural, and educational contexts of individual schools rather than treated as a rigid instructional sequence. These considerations provide important directions for the future development, implementation, and empirical evaluation of the proposed framework.

Conclusion

Environmental education needs to move beyond the transmission of information towards developing ecological understanding, values, attitudes, and responsible practices. This paper highlights the integration of ecocentrism as a philosophical foundation and experiential learning as a pedagogical approach to promote transformative environmental education. While ecocentrism emphasises the intrinsic value of nature, ecological interconnectedness, and respect for biodiversity, experiential learning enables students to develop these perspectives through direct experiences, reflection, conceptual understanding, and practical engagement.

The proposed Integrated Ecocentric Experiential Learning Framework (IEELF) brings these perspectives together through five interconnected dimensions: Direct Experience with Nature, Ecological Reflection, Ecocentric Conceptual Understanding, Ecological Engagement and Responsible Action, and Evaluation and Reflective Transformation. It offers a conceptual pathway for nurturing ecological values, environmental concern, ecological responsibility, and pro-environmental attitudes among school students.

The framework also highlights the importance of nature-based learning, ecological activities, teacher preparation, and curriculum integration in school education. Although implementation may involve challenges related to time, resources, and assessment, context-sensitive planning can create meaningful learning opportunities. Further empirical investigation is necessary to examine the framework's applicability and potential contribution to environmental education. Ultimately, environmental education should enable learners not merely to understand nature, but also to value, respect, and act responsibly towards the natural world.
