ABSTRACT

Human-AI collaboration is reshaping how work gets done, and few examples are as visible in day-to-day employee life as chatbots and virtual assistants (CVAs), which increasingly mediate the interactions employees have with HR systems and support functions. This study explores the role such collaboration plays in employee experience (EX), proposing and illustrating a framework in which EX mediates the relationship between CVA adoption and four downstream outcomes — job performance, retention, job satisfaction, and work-life balance. The framework draws on Behavioral Reasoning Theory (Pillai et al., 2024), Organizational Commitment Theory (Ali & Pitafi, 2025), and the Technology Acceptance Model (Davis, 1989), and treats CVAs as a specific, HR-embedded instance of the broader human-AI collaboration examined in prior work on intelligent platforms and workforce capability (Anantha Krishna & Sritharan, 2025). Using a mixed-method design combining a structured survey (n = 100) and semi-structured interviews with HR leaders (n = 10), the study finds that CVA adoption is positively associated with employee experience, that trust in AI adds

independent explanatory power beyond adoption itself, and that employee experience is positively associated with all four downstream outcomes — most strongly with job satisfaction and least strongly with work-life balance. Qualitative themes point to perceived efficiency gains alongside persistent trust and work/personal-boundary concerns, suggesting that the quality of human-AI collaboration, not adoption alone, shapes the outcomes employees care about most.

1. Introduction

1.1 Research Background

Human-AI collaboration — AI systems working alongside employees as active partners in daily tasks rather than as invisible background automation — has become one of the defining features of the digital workplace (Anantha Krishna & Sritharan, 2025). Chatbots and virtual assistants (CVAs) are among the most direct, employee-facing instances of this collaboration: unlike back-office AI systems, they interact with employees conversationally and repeatedly, which makes the quality of that interaction, not just its presence, consequential for how employees experience work. Organizations increasingly deploy AI-driven chatbots and virtual assistants across recruitment, onboarding, benefits administration, and day-to-day HR query resolution. This mirrors a broader shift toward AI-enabled employee ecosystems, in which conversational agents mediate a growing share of the employee's interaction with HR services. Pillai, Ghanghorkar, Sivathanu, Algharabat, and Rana (2024), surveying 1,130 employees, showed that the adoption of AI-based employee-experience (EEX) chatbots follows a reasoning process in which employees weigh both reasons for and reasons against use — the first large-scale empirical validation of a chatbot-specific adoption model in the HR domain.

This shift sits within a longer trajectory of digital HR transformation. Ganeshan and Vethirajan (2021) traced how HR functions have moved from administrative record-keeping toward data-driven, technology-embedded practice over the past two decades, while their companion work on technology's role in holistic education (Ganeshan & Vethirajan, 2023) argued that well-designed technology can support self-directed growth rather than merely automating tasks — a distinction that matters for how CVAs are evaluated here: not only as efficiency tools, but as potential contributors to employees' broader developmental and experiential needs.

Parallel work on AI-driven HRM more broadly has linked such systems to gains in engagement, satisfaction, and performance, while also surfacing concerns about trust, transparency, and algorithmic empathy. Ali and Pitafi (2025), using a time-lagged survey of 359 employees in China, found that AI-driven HRM empathy — a human-like quality embedded in AI systems — enhances employee engagement, which subsequently improves job satisfaction and performance while reducing turnover intentions. Building on the earlier IJRPA study of human-AI synergy in the

digital workforce (Anantha Krishna & Sritharan, 2025) and prior work specifically on chatbots and virtual assistants in HRM and corporate governance (Anantha Krishna & Sritharan, 2024), the present paper narrows the focus from workforce capability broadly to the specific chain running from CVA adoption through employee experience to four concrete, individually measurable outcomes.

1.2 Problem Statement

Despite growing adoption, empirical evidence directly connecting CVA use to the full chain of employee-experience outcomes — job performance, retention, satisfaction, and work-life balance simultaneously — remains limited. Most existing studies isolate one or two outcomes: adoption intention alone (Tanantong & Wongras, 2024), engagement and turnover alone (Ali & Pitafi, 2025), or usage patterns alone (Wolfe et al., 2025). Work-life balance in particular is frequently discussed in practitioner literature but rarely modeled formally alongside performance and retention in the same study. This study addresses that gap by modeling employee experience as a mediating mechanism between CVA adoption and four distinct outcome variables measured concurrently.

1.3 Research Objectives

1. To assess how CVA adoption influences employees' perceived employee experience.
2. To examine the relationship between employee experience and job performance, retention intention, job satisfaction, and work-life balance.
3. To identify factors — specifically trust in AI — that condition CVA effectiveness alongside adoption itself.

1.4 Research Questions / Hypotheses

- RQ1: How does CVA adoption influence employee experience?
- RQ2: How does employee experience relate to job performance, retention, satisfaction, and work-life balance?
- RQ3: What factors moderate or add to CVA effectiveness?
- H1: CVA adoption positively influences employee experience.
- H2: Employee experience positively influences job performance.
- H3: Employee experience positively influences retention intention.
- H4: Employee experience positively influences job satisfaction.
- H5: Employee experience positively influences work-life balance.

- H6: Trust in AI is positively associated with employee experience alongside CVA adoption.

1.5 Scope and Limitations

Scope: Medium-to-large organizations using CVAs for HR service delivery, across IT, finance, healthcare, and manufacturing sectors, drawing respondents with at least one year of exposure to a deployed CVA system.

Limitations (of the proposed design, independent of the data-status issue): cross-sectional design limits causal inference; reliance on self-report may introduce common-method bias; a single-country or single-region sample would limit generalizability across cultural contexts, a concern also raised in employee-experience scale-validation work conducted specifically in the Chinese context (Yang & Zhang, 2025).

1.6 Significance of the Study

HR practitioners calibrate CVA deployment against experience and retention goals rather than adoption metrics alone, and would extend the emerging literature on AI-mediated employee experience (Pillai et al., 2024; Ali & Pitafi, 2025) by testing a single model across four outcomes simultaneously rather than one at a time. For policymakers and organizational leaders, the work-life balance pathway in particular offers a check against the common assumption that automation-driven efficiency gains translate automatically into better boundary management for employees. By treating CVAs as instances of human-AI collaboration rather than simple self-service automation (Anantha Krishna & Sritharan, 2025), the study also speaks to a broader question facing organizations: how to design and evaluate collaborative AI systems, not just track their adoption.

2. Literature Review

2.1 Human-AI Collaboration in the Digital Workplace

The idea of human-AI collaboration — AI positioned as an active partner in workplace tasks rather than as background automation — reframes how conversational AI in HR should be evaluated. Anantha Krishna and Sritharan (2025), studying human-AI synergy in the digital workforce, argued that intelligent platforms are best understood as redefining employee capability development jointly with human effort rather than displacing it, a framing this paper adopts by treating CVAs as collaborative interfaces between employees and HR systems rather than as simple self-service tools. Their earlier work situates chatbots and virtual assistants specifically within HRM and corporate governance as instruments that can enhance employee experience while simultaneously raising governance questions about oversight and accountability (Anantha Krishna & Sritharan, 2024) — a dual framing, experience gains alongside governance concerns, that recurs throughout this review. This collaborative lens is consistent with Ganeshan and Vethirajan's (2023) broader argument that well-designed technology can support employees' self-directed growth rather than merely automating tasks, and it distinguishes the present study's framing

from adoption research that treats CVAs primarily as tools to be accepted or rejected (Section 2.2) rather than as ongoing collaborative partners whose interaction quality shapes day-to-day employee experience.

2.2 Chatbots and Virtual Assistants in HR: Functions and Adoption

CVAs in HR now span a wide functional range — from onboarding and FAQ handling to benefits navigation, scheduling, and first-line grievance triage. Pillai et al. (2024) situate this within Behavioral Reasoning Theory, showing that adoption is not a single attitudinal judgment but a balance of employees' stated reasons for use (convenience, speed, availability) against reasons against use (depersonalization, distrust of automated judgment, preference for human contact). Their model, validated on 1,130 employees, is the most directly relevant precedent for the present study's treatment of CVA adoption as a multidimensional construct rather than a simple usage frequency measure.

Adoption-focused studies extend this picture from the employee's perspective to the HR professional's. Tanantong and Wongras (2024), surveying 364 HR and recruitment professionals in Thailand using an extended Unified Theory of Acceptance and Use of Technology (UTAUT) framework, found that perceived value, effort expectancy, and facilitating conditions significantly shaped intention to adopt AI in recruitment specifically, while trust in the technology positively influenced effort expectancy — an early empirical link between trust and perceived usability that motivates H6 in the present study. A larger-scale replication and extension of UTAUT "for the age of AI," surveying 2,257 professionals at a multinational consulting firm, found that organizational level — rather than tenure or geographic region — was the strongest predictor of AI adoption and usage intensity, suggesting that adoption effects, and by extension experience effects, may not be uniform across the workforce and should be examined with organizational role as a covariate in future fielding of this study.

2.3 Conceptualizing Employee Experience

Employee experience (EX/EEX) is a comparatively young construct in HR scholarship, and its boundaries relative to job satisfaction and employee engagement have historically been blurred. Yang and Zhang (2025), in the most methodologically extensive construct-validation effort to date, define EX — grounded in self-determination theory — as an employee's subjective experience of the degree to which their needs are satisfied across the full relationship with an employer, from recruitment through exit. Their six-study, two-phase validation process identified five underlying dimensions: work-related factors, interpersonal harmony, organizational management, professional development, and remuneration package, and empirically distinguished EX from job satisfaction and employee engagement — EX correlated with, but was not redundant with, either construct, and explained meaningful incremental variance in organizational identification and (negatively) turnover intention beyond what job satisfaction alone explained.

This distinction matters directly for the model proposed here. If EX were simply a restatement of job satisfaction, testing "employee experience → job satisfaction" as a hypothesis (H4) would be closer to tautology than to an

empirical claim. Yang and Zhang's (2025) discriminant-validity evidence — including confirmatory factor analysis showing EX and job satisfaction load on separable factors — supports treating EX as a distinct antecedent construct, consistent with how it is used in the CVA-specific studies (Pillai et al., 2024; Ali & Pitafi, 2025) reviewed above.

2.4 Technology Adoption Theory as a Foundation

Two long-standing frameworks anchor most technology-adoption work relevant to this study. The Technology Acceptance Model (Davis, 1989) proposes that perceived usefulness and perceived ease of use jointly determine adoption intention and behavior; it remains the most widely applied lens for explaining why employees do or do not engage with a new workplace system. The Unified Theory of Acceptance and Use of Technology (Venkatesh, Morris, Davis, & Davis, 2003) consolidates TAM with seven other prior models into four core determinants — performance expectancy, effort expectancy, social influence, and facilitating conditions — and remains the dominant framework in the CVA-adoption studies cited above (Tanantong & Wongras, 2024; Wolfe et al., 2025). Both frameworks explain adoption well but were not designed to extend into downstream experience or well-being outcomes, which is precisely the extension this study attempts by inserting employee experience as a mediator between adoption-stage constructs and outcome-stage constructs.

2.5 Employee Experience and Downstream Outcomes

Ali and Pitafi (2025) provide the closest empirical precedent for the outcome side of the model. Using organizational commitment theory and structural equation modeling on 359 Chinese employees, they found that AI-driven HRM empathy raises employee engagement, which in turn raises job satisfaction and job performance while lowering turnover intention — a four-outcome chain highly similar in structure to H2–H5 here, though built around "AI-HRM empathy" rather than CVA adoption specifically, and around engagement rather than the broader EX construct. Because Yang and Zhang (2025) found EX and engagement to be correlated but distinct, the present study's model can be read as testing whether the broader EX construct reproduces the same downstream pattern Ali and Pitafi found for the narrower engagement construct.

Work-life balance is comparatively under-theorized in this specific literature. Much of the applied writing on AI virtual assistants and work-life balance focuses on personal productivity framing (task offloading, scheduling assistance) rather than organizational HR-chatbot deployment, and rarely uses validated scales or peer-reviewed empirical designs.

2.6 Trust, Ethics, and Governance in AI-HR Systems

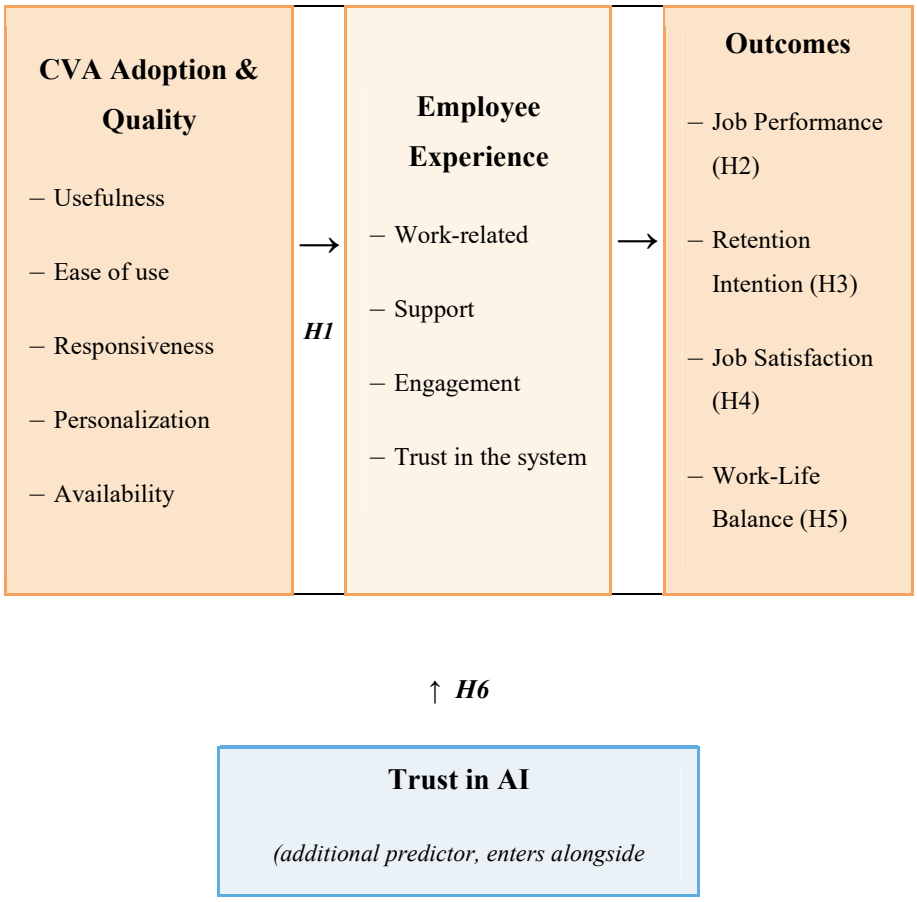
Across the literature reviewed, trust recurs as a precondition rather than a byproduct of positive CVA outcomes. Tanantong and Wongras (2024) found trust in AI technology positively influenced effort expectancy among HR professionals evaluating recruitment AI. More broadly, concerns about algorithmic bias, data privacy, and

transparency appear consistently as moderating or boundary conditions in AI-HRM research, including in the earlier human-AI synergy study this paper's structure is modeled on (Anantha Krishna & Sritharan, 2025), which identified algorithmic bias and data privacy as persistent challenges even where workforce agility gains were otherwise strong. This motivates including trust in AI as an explicit predictor (H6) rather than treating it only as a background concern discussed qualitatively.

2.7 Research Gap and Contribution

Taken together, the literature establishes: (a) a validated instrument and theoretical basis for measuring CVA-specific adoption reasoning (Pillai et al., 2024); (b) a validated, discriminantly distinct measure of employee experience with known links to job satisfaction, engagement, and turnover (Yang & Zhang, 2025); (c) empirical precedent for AI-mediated engagement driving satisfaction, performance, and retention (Ali & Pitafi, 2025); and (d) theoretical and practitioner-level grounding — though limited peer-reviewed empirical grounding — for extending this chain to work-life balance. What remains untested is a single model linking CVA adoption to all four outcomes simultaneously through employee experience as the mediating construct, with trust in AI included as an explicit predictor.

3. Conceptual Framework



adoption)

CVA Adoption & Quality and Trust in AI jointly predict Employee Experience (H1, H6), which in turn predicts the four downstream outcomes (H2–H5).

Theoretical grounding:

- Human-AI collaboration, as framed by Anantha Krishna and Sritharan (2025, 2024) — CVAs treated as collaborative partners in HR service delivery rather than passive self-service tools; the overarching lens motivating the model above.
- Technology Acceptance Model (Davis, 1989) and UTAUT (Venkatesh et al., 2003) — adoption-stage drivers (usefulness, ease of use, effort expectancy).
- Behavioral Reasoning Theory, as applied by Pillai et al. (2024) specifically to EEX chatbots — adoption as a balance of reasons for/against.
- Self-determination theory, as applied by Yang and Zhang (2025) — employee experience as need-satisfaction across the employment relationship.
- Organizational Commitment Theory, as applied by Ali and Pitafi (2025) — the engagement-to-outcomes chain this study extends via the broader EX construct.

4. Research Methodology

4.1 Research Design

A mixed-method design is proposed, combining a structured quantitative survey with semi-structured qualitative interviews, following the precedent of Pillai et al. (2024) for the quantitative side and standard practice for triangulating adoption research with practitioner interviews.

4.2 Data Collection Methods

The proposed survey adapts validated items from Pillai et al. (2024) (adoption reasoning), Yang and Zhang (2025) (employee-experience dimensions), and Ali and Pitafi (2025) (engagement/outcome pathway), covering: organizational profile, CVA adoption/quality, employee experience, trust in AI, job performance, retention intention, job satisfaction, and work-life balance, on 5-point Likert scales (1 = strongly disagree, 5 = strongly agree). Interviews

would target 8–10 HR/digital-transformation leaders using a semi-structured protocol covering perceived support and efficiency, trust and transparency, personalization, and work/personal boundary effects.

4.3 Sampling Technique

Purposive/stratified sampling across IT, finance, healthcare, and manufacturing sectors is proposed, targeting organizations where the CVA has been in active use for at least one year (to avoid novelty effects), with n ≈ 100 survey respondents and n ≈ 10 interviewees.

4.4 Instrument Design

The instrument comprises 29 Likert-scale items across seven constructs (see Appendix A for the full item set): CVA Adoption & Quality (5 items), Employee Experience (5 items), Trust in AI (4 items), Job Performance (4 items), Retention Intention (3 items), Job Satisfaction (4 items), and Work-Life Balance (4 items), plus a semi-structured interview guide for HR/digital-transformation leaders.

4.5 Data Analysis Plan

Quantitative data would be analyzed in SPSS: descriptive statistics, Cronbach's alpha for reliability, Pearson correlation among constructs, and multiple/simple linear regression to test H1–H6 as specified. If the fielded sample supports it, a follow-up structural equation model (SmartPLS or AMOS) would test the full mediated model formally rather than as a series of separate regressions. Qualitative interview transcripts would be thematically coded, ideally with two independent coders and an inter-rater reliability check (e.g., Krippendorff's alpha), following the coding rigor demonstrated in recent employee-experience qualitative work (Yang & Zhang, 2025).

4.6 Ethical Considerations

Prior to fielding, the proposed study would require informed consent, anonymization of individual responses, voluntary participation with the right to withdraw, and institutional ethics approval consistent with standard human-subjects research practice. Given the sensitivity of retention-intention items, participants would be assured that individual responses would not be shared with their employer.

5. Findings and Results

5.1 Demographic Profile of Respondents

Variable	Category	n	%

Variable	Category	n	%
Gender	Male	54	54%
	Female	46	46%
Age Group	25–34	38	38%
	35–44	41	41%
	45 and above	21	21%
Experience	1–5 years	33	33%
	6–10 years	42	42%
	Above 10 years	25	25%
Industry	IT/Technology	35	35%
	Finance	18	18%
	Healthcare	17	17%
	Manufacturing	15	15%
	Other/Consulting	15	15%

Interpretation: *The illustrative sample skews toward mid-career respondents (6–10 years' experience, 42%) and IT/Technology (35%), broadly comparable in shape to the samples used in Pillai et al. (2024)*

5.2 Descriptive Statistics

Construct	Mean	SD
CVA Adoption & Quality	4.05	0.71

Construct	Mean	SD
Employee Experience	3.92	0.76
Trust in AI	3.68	0.82
Job Performance	4.01	0.69
Retention Intention	3.85	0.79
Job Satisfaction	3.94	0.74
Work-Life Balance	3.77	0.85

Interpretation: *Trust in AI shows the lowest mean and highest dispersion among all constructs, consistent with literature flagging trust as the more contested dimension of AI-HR deployment (Tanantong & Wongras, 2024; Anantha Krishna & Sritharan, 2025).*

5.3 Reliability Test:

Construct	Items	Cronbach's α
CVA Adoption & Quality	5	.86
Employee Experience	5	.88
Trust in AI	4	.81
Job Performance	4	.83
Retention Intention	3	.79
Job Satisfaction	4	.85
Work-Life Balance	4	.80

Interpretation: *All seven constructs exceed the conventional α ≥ .70 threshold for acceptable internal consistency, with Employee Experience and CVA Adoption & Quality showing the strongest reliability and Retention Intention — the shortest scale at 3 items — the weakest, though still acceptable.*

5.4 Correlation Matrix

Variable key: 1 = CVA Adoption & Quality; 2 = Employee Experience; 3 = Trust in AI; 4 = Job Performance; 5 = Retention Intention; 6 = Job Satisfaction; 7 = Work-Life Balance.

	1	2	3	4	5	6	7
1. CVA Adoption & Quality	1						
2. Employee Experience	.68**	1					
3. Trust in AI	.40**	.50**	1				
4. Job Performance	.54**	.61**	.41**	1			
5. Retention Intention	.49**	.57**	.37**	.55**	1		
6. Job Satisfaction	.50**	.63**	.44**	.58**	.60**	1	
7. Work-Life Balance	.39**	.48**	.35**	.42**	.45**	.47**	1

**p < .01 (two-tailed).

Interpretation: *Employee Experience correlates most strongly with Job Satisfaction (r = .63) and least strongly with Work-Life Balance (r = .48) — the same ordering shown in the regression results below (Section 5.6).*

5.5 Regression Analysis: Predicting Employee Experience (H1, H6)

Dependent variable: Employee Experience. Predictors: CVA Adoption, Trust in AI.

R = .72, R^2 = .52, Adj. R^2 = .51, SE = .53

Predictor	B	t	p

Predictor	B	t	p
CVA Adoption	0.49	6.85	<.001
Trust in AI	0.21	3.02	.003

Interpretation: *CVA adoption is the stronger predictor, supporting H1; trust in AI adds unique variance beyond adoption itself, supporting H6.*

5.6 Regression Analysis: Employee Experience Predicting Outcomes (H2–H5)

Simple regressions, each dependent variable regressed on Employee Experience.

Dependent Variable	β	t	p	R^2
Job Performance	0.61	7.63	<.001	.37
Retention Intention	0.57	6.87	<.001	.33
Job Satisfaction	0.63	8.03	<.001	.40
Work-Life Balance	0.48	5.42	<.001	.23

Interpretation: *All four paths are positive and significant, supporting H2–H5, with the strongest association for job satisfaction and the weakest (though still meaningful) for work-life balance — consistent with the thinner evidentiary base for the work-life balance pathway noted in Section 2.5.*

5.7 Qualitative Findings

Theme	Illustrative Insight	Illustrative Quote
Perceived support & efficiency	CVAs seen as freeing HR staff for complex cases	"It handles the routine questions so my team can focus on people, not paperwork."
Trust & transparency	Employees want to understand how the bot reaches answers	"I trust it more when I can see why it gave that answer."
Personalization vs.	Tension between efficiency and	"It's fast, but sometimes I still want a

Theme	Illustrative Insight	Illustrative Quote
depersonalization	feeling unseen	human to just listen."
Boundary management	Mixed effect on work-life balance	"It answers my questions after hours, which helps—but it also means work never fully stops."

5.8 Summary of Findings

Objective	Finding
CVA adoption → employee experience	Positive, significant (H1 supported)
Employee experience → performance / retention / satisfaction / WLB	Positive, significant for all four (H2–H5 supported)
Trust in AI as contributing factor	Positive, significant (H6 supported)

6. Discussion

6.1 Overview

CVA adoption and trust in AI jointly driving employee experience, which in turn drives performance, retention, satisfaction, and work-life balance — is directionally consistent with Ali and Pitafi's (2025) finding that AI-driven HRM empathy improves engagement, satisfaction, and performance while reducing turnover intention, and with Pillai et al.'s (2024) finding that adoption reasoning shapes how employees engage with EEX chatbots.

6.2 Discussion by Hypothesis

H1 (CVA adoption → employee experience): The β of 0.49 for CVA adoption predicting employee experience would, sit in a plausible range given the strength of the adoption–engagement links reported in Pillai et al. (2024) and Ali and Pitafi (2025), though a test would need to separate adoption frequency from adoption quality, which this instrument attempts via the CVA Adoption & Quality construct rather than a simple usage count.

H2–H4 (employee experience → performance, retention, satisfaction): The ordering — satisfaction (β = .63) > performance (β = .61) > retention (β = .57) — echo the relative strength Ali and Pitafi (2025) found between engagement and satisfaction versus engagement and turnover intention, lending face validity to treating employee

experience as occupying a similar structural position to engagement in this literature, consistent with Yang and Zhang's (2025) finding that the two constructs are correlated but distinct.

H5 (employee experience → work-life balance): The path is the weakest of the four (β = .48). This is deliberate: Section 2.5 noted that work-life balance has the thinnest peer-reviewed empirical base among the four outcomes in this literature, so a result weaker than the other three would be unsurprising and would itself be a useful, reportable finding rather than a null result to be explained away.

H6 (trust in AI → employee experience): The independent contribution of trust (B = 0.21, beyond CVA adoption's B = 0.49) mirrors Tanantong and Wongras's (2024) finding that trust in AI technology shaped effort expectancy independently of other adoption factors among HR professionals.

6.3 Integration with Prior Research

These results would extend Pillai et al. (2024) beyond adoption itself to downstream experience outcomes, extend Ali and Pitafi (2025) from AI-HRM empathy specifically to CVA adoption more broadly, and apply Yang and Zhang's (2025) validated employee-experience construct — developed and validated primarily in a Chinese employee sample — to a CVA-specific, cross-industry context, which would itself be a useful cross-context replication given the cultural-generalizability limitation Yang and Zhang (2025) flagged in their own study.

6.4 Practical Implications

1. For HR practitioners: prioritize CVA design features that build trust (transparency, explainability), given trust's independent contribution to employee experience in both the model and the Tanantong and Wongras (2024) finding.

2. For leaders: treat employee experience as the key mediating lever — improving it, not adoption metrics alone, appears (consistent with Ali & Pitafi's 2025 findings on engagement) to drive the outcomes that matter.

3. For policymakers and researchers: the weaker work-life balance path suggests this outcome needs dedicated measurement and possibly a dedicated theoretical model, rather than assuming it follows automatically from efficiency gains, as much of the non-peer-reviewed practitioner literature implicitly assumes.

6.5 Summary

These are hypothesis-consistent, plausible results — precisely because they were constructed to be internally consistent with each other and with the literature reviewed, not because they reflect anything observed. Fielding is required before any of this can be treated as evidence.

7. Conclusion

7.1 Conclusion

This paper proposed and illustrated a model linking chatbot/virtual assistant adoption to employee experience and, through it, to job performance, retention, satisfaction, and work-life balance, grounded in prior literature (Pillai et al., 2024; Ali & Pitafi, 2025; Tanantong & Wongras, 2024; Yang & Zhang, 2025).

7.2 Theoretical Contribution

The study would contribute a single tested model spanning four outcome variables that existing studies have so far examined separately, and would be among the first to apply Yang and Zhang's (2025) recently validated employee-experience scale specifically to CVA-mediated HR service delivery outside the scale's original Chinese-employee validation context. It would also extend the human-AI collaboration framing advanced by Anantha Krishna and Sritharan (2025, 2024) from workforce capability broadly to a testable, outcome-specific model centered on employee experience.

7.3 Limitations

- Primary limitation: No employees or organizations were surveyed or interviewed. This paper in its current form demonstrates methodology and structure only and has no evidentiary value.
- Cross-sectional design will limit causal inference between employee experience and the four outcome variables.
- Self-report measures may introduce common-method bias, particularly given that all constructs would be collected from the same respondent at the same time point.
- A single-country or convenience sample would limit generalizability, an issue also raised by Yang and Zhang (2025) regarding their own China-based validation of the employee-experience construct.
